Customized execution of backup jobs

EasySave makes the selection of backup jobs extremely flexible, giving users the ability to choose precisely which backups to run.

For example, by entering "1-3.5", the system will run jobs 1-3 and job 5 in a single operation.

This simplified method allows you to select ranges of tasks (such as "1-3") and add individual tasks (such as "5") by separating them with commas, making it easy to customize your backups.

Extended backup location support

Compatible with various types of storage, including local, external and network drives.

Daily logging

Detailed monitoring of backup operations is recorded daily in a log file in JSON format. This file includes information such as timestamp, job name, source and target file paths, file size and transfer duration.

Real-time monitoring

A status file in JSON format, updated in real time, lets you track the progress of your backups. It displays the number of files remaining to be backed up, as well as their total size.

In addition to being able to view the progress of your backups in this file, you also have the option of tracking the progress of backup tasks directly on the application as these tasks are executed.

File configuration and location

Locations for log and status files have been optimized to work reliably on customer servers, avoiding standard local paths and making JSON files easier to access and read.

Easy Save

Introduction

livable 1 contains the first functional version of EasySave, as specified by ProSoft.

This version initiates the development of a .NET Core console application for managing backup tasks.

Prerequisites

1. Installation process

- Clone the livable-1 branch and open the project with Visual Studio 2022.
- Make sure you have installed .NET Core 6.0.

2. Software dependencies

- .NET Core 6.0
- Visual Studio 2022

Execute Easy Save

Windows

Run EasySave.exe in directory `../G4-FISA-24/EasySave-G4-FISA-24/EasySave/bin/Debug/net6.0/EasySave.exe`.

Linux

Run `./EasySave` after publishing from visual studio.

Publishing EasySave

You need to specify the 'Target runtime' according to the operating system.

Tests

Open the Test Explorer in Visual Studio and run the unit tests.

All tests are tested during the CI/CD phase, but it's best to run the tests before pushing.

Latest versions

Please consult the "releases" tab to access the latest version of livrable 1 (Pipelines -> Releases):

Features

- Sequential backup
- Daily logs
- Status logsv
- Select language
- List jobs
- Load job configuration
- Create a job
- Delete a job
- Launch jobs

Console application entry point

```
using View = EasySave.Views.View;
namespace EasySave // Note: actual namespace depends on the project name.
{
    /// <summary>
    /// Application entry point
    /// </summary>
    internal class Program
    {
        [STAThread]
        static void Main(string[] args)
        {
            View pView = new View();
            //Lance le program principale
            pView.Run();
        }
    }
}
```

Architecture

The architecture is based on an MVVM model with :

- **Models** : classes representing data ([CJob](#), [CJobManager](#), [CSettings](#), etc.)
- **Views**: classes representing views ([BaseView](#), [View](#), [JobView](#), etc.).
- **ViewModels**: classes linking models and views.

Log System

Default location of [CJobManager](#) and [CSettings](#) and location of [log_model](#) stored using the logging classes in the [Logs](#) package.

The current location of event logs is stored in the **Logs** folder.

The current location of user settings is stored in the root directory **Settings.json**.

The location of backup jobs is stored in the **Jobs** folder.

Logs with names formatted as **Logs - 2024-02-15** are daily logs.

The `Logs.json` file is the log status.

Continuous Integration (CI) and Continuous Deployment (CD) processes using Azure DevOps

Continuous Integration configuration

Triggering pipelines

Continuous integration pipelines are configured to trigger automatically when a pull request is made to the main branch. Continuous integration validation is a prerequisite for any code merge.

Integration process

- Build: Compilation of source code into an executable or deployable package.
- Automated Testing: Execution of tests to verify code quality and functionality.
- Release Publishing: Creation and storage of release artifacts in Azure DevOps.
